Malignant pleural mesothelioma (MPM) is an aggressive tumor with poor prognosis for which an effective therapy remains to be established. Our study investigated the therapeutic potential of the suppressor of cytokine signaling 3 (SOCS3), an endogenous inhibitor of intracellular signaling pathways, for treatment of MPM. We infected MPM cells (H226, EHMES-1, MESO-1 and MESO-4) with an adenovirus-expressing SOCS3 (AdSOCS3) to examine the effect of SOCS3 overexpression on MPM cells. SOCS3 overexpression reduced MPM proliferation and induced apoptosis and partial G0/G1 arrest. SOCS3 also inhibited the proliferation of MPM cells via multiple signaling pathways including Janus kinase (JAK)/signal transducer and activator of transcription 3 (STAT3), extracellular signal-regulated kinase (ERK), focal adhesion kinase (FAK) and p53 pathways. Notably, AdSOCS3 treatment inhibited tumor growth in an MPM pleural xenograft model. These findings demonstrate that overexpression of SOCS3 has a potent antitumor effect against MPM both in vitro and in vivo and indicate the potential for clinical use of SOCS3 for MPM treatment.

Malignant pleural mesothelioma (MPM) is an aggressive tumor arising from the mesothelial cells of serosal cavities. MPM may be asymptomatic at the early stage and is sometimes observed incidentally during routine chest radiography. Common symptoms include chest pain and dyspnea, which are caused by tumor invasion of the chest wall or pleural effusion and occur late during disease progression. Although chemotherapy with the drug pemetrexed improves survival time for unresectable MPM patients, the overall median survival time is only 12 months.1 MPM is often associated with past exposure to asbestos, in which case there is a long latency period, often exceeding 20 years, between first exposure to asbestos and diagnosis of MPM.2 The number of deaths from MPM is expected to increase in the next 20 years world-wide where heavy use of asbestos has occurred.2–5 There is thus a growing need for the development of new therapies to treat this disease.

A growing number of studies of MPM tumor biology have established important roles for cytokines involved in tumor growth or the spread of this disease.6–10 A reported potential molecular target for MPM therapeutics is the interleukin-6 (IL-6)/Janus kinase (JAK)/signal transducer and activator of transcription 3 (STAT3) signaling pathway and

high-level expression of IL-6 in the pleural fluid of MPM patients. The binding of IL-6 to its cognate receptor leads to a conformational change in the receptor that initiates the activation of JAK, which in turn activates the transcription factor STAT3 to dimerize and translocate into the nucleus, thus leading to the initiation of target gene transactivation. This pathway is crucial for the occurrence of hematopoiesis, immune response and oncogenesis. Moreover, dysfunction of the regulatory system for the JAK/STAT3 pathway has been demonstrated to be involved in the development of cancer.

The suppressor of cytokine signaling (SOCS) family proteins participate in the negative regulation of multiple signaling pathways including the IL-6/JAK/STAT3 signaling pathway, while SOCS3 can bind both the cytokine receptor and JAK, thus facilitating inhibition of the JAK molecule. The restoration of SOCS3 expression in several cancer cell lines was found to effectively suppress tumorigenicity. Because the JAK/STAT3 signaling pathway is frequently activated in a wide variety of human malignancies, SOCS3 gene delivery may represent a novel therapeutic strategy for the treatment of human cancers, including mesothelioma.

In addition to the IL-6/JAK/STAT3 signaling pathway, various other signaling pathways are associated with tumorigenesis in MPM. Among these pathways, activators of oncogenic molecules such as the extracellular signal-regulated kinase (ERK) and focal adhesion kinase (FAK) have been implicated. It was reported that SOCS3 participated in the inhibition of ERK phosphorylation and the degradation of FAK. SOCS3 can competitively block receptor recruitment of SH2-domain-containing tyrosine phosphatase (SHP-2) to Tyr759 of gp130, thus inhibiting ERK activation. Interactions of SOCS3 with FAK through the Src homology 2 (SH2) domain have been reported to promote polyubiquitination and subsequent degradation of FAK. Because there are multiple abnormalities in signal transduction and genetic differences in individual patients, SOCS3, which, as seen above, is involved in the regulation of multiple signals, is expected to be effective for the treatment of MPM. However, the potential therapeutic benefits of SOCS3 for MPM have not yet been investigated. In the study presented here, we investigated the efficacy of SOCS3 gene delivery for the treatment of MPM.

Material and Methods

Cell lines
Mesothelioma cell lines H28, H226 and H2452 were purchased from American Type Culture Collection (Manassas, VA). Mesothelioma cell line EHMES-1 was kindly provided by Dr. Hironobu Hamada (Ehime University, Ehime, Japan). ACC-MESO-1 (MESO-1) and ACC-MESO-4 (MESO-4) cell lines were purchased from RIKEN BRC cell bank (Tsukuba, Japan). All the cells were cultured in RPMI 1640 (Wako, Osaka, Japan) with 10% fetal calf serum (FCS) (HyClone Laboratories, Logan, UT), 100 IU/mL penicillin and 100 μg/mL streptomycin (Nacalai Tesque, Kyoto, Japan). Human adult mesothelial cells were purchased from Zen-Bio (Research Triangle Park, NC) and cultured in Mesothelial Cell Growth Medium (Zen-Bio). HEK293 cells were obtained from the JCRB Cell Bank (Tokyo, Japan) and cultured in DMEM (Wako) with 10% FCS (HyClone), 100 IU/mL penicillin and 100 μg/mL streptomycin (Nacalai Tesque).

Reagents
Recombinant human IL-6 was kindly provided by Dr. Kazuyuki Yoshizaki (Osaka University, Osaka, Japan), recombinant soluble IL-6 receptor (sIL-6R) and anti-IL-6R monoclonal antibody (tocilizumab, currently known as MRA) were obtained from Chugai Pharmaceutical Co. (Tokyo, Japan). Purified human IgG, purchased from Sigma (St. Louis, MO), was used as control for MRA. JAK inhibitor I and PD98059 were purchased from Calbiochem (La Jolla, CA) and doxorubicin from Wako.

Preparation of adenoviruses
Replication-defective recombinant adenoviral vectors were constructed with the cosmid–adenoviral DNA terminal protein complex method. Adenoviral vectors AdLacZ and adenovirus-expressing SOCS3 (AdSOCS3) were designed to express the LacZ gene and the human SOCS3 gene, respectively, under the control of the CAG promoter (a modified chicken β-actin promoter with a cytomegalovirus immediate early enhancer). Solutions of these adenoviral vectors were prepared as described previously and stored at −80°C until use. Adenoviral vectors containing the genes for HA-tagged Y705F dominant-negative STAT3 (AddnSTAT3) were kindly provided by Dr. Akihiko Yoshimura (Keio University, Tokyo, Japan).

X-gal staining
The transduction efficiency of adenoviral vectors was assessed by means of X-gal staining. Cells were cultured in 6-well plates at a density of 1 × 10⁶ cells per well and infected with AdLacZ at the indicated multiplicities of infection (MOIs). X-gal staining was performed 24 hr after infection according to the protocol provided by the manufacturer (Sigma-Aldrich, St. Louis, MO).

Reverse transcription-polymerase chain reaction analysis
Total RNA of cultured cells was isolated with Sepasol-RNA I (Nacalai Tesque) and cDNAs were synthesized from 500 ng of each total RNA preparation with a Quantitect Reverse Transcription kit (QIAGEN, Valencia, CA), all according to the manufacturers’ instructions. The TaKaRa Ex Taq (Takara Bio, Otsu, Shiga, Japan) was used for reverse transcription-polymerase chain reaction (RT-PCR) analysis. β-actin was used as a housekeeping gene to evaluate and compare the quality of different cDNA samples. Primers for β-actin (67°C annealing, 33 cycles) were: forward, 5'-AGCCTCGCTTTTGCGGA-3';
reverse, 5'-CTGGTGCCCTGGGGCG-3'. Primers for SOCS3 (55°C annealing, 33 cycles) were: forward, 5'-TCAAGACCTTCAGCTCCAAG-3'; reverse, 5'-TGACGCTGAGCTGGAAGAA-3'. And primers for p53 (60°C annealing, 33 cycles) were: forward, 5'-CCCAGGCGAAAGAACC-3'; reverse, 5'-TCAAGGCTCATTGCTCT-3'. PCR products were detected by means of 1% agarose gel electrophoresis with ethidium bromide staining.

Small interfering RNA transfection
Commercial JAK1 small interfering RNA (siRNA) was obtained from QIAGEN. Cells were transfected with siRNA using Lipofectamine 2000 reagent (Invitrogen, Carlsbad, CA) according to the manufacturer’s instructions. Nonspecific siRNA (QIAGEN) was used as a negative control, and the selective silencing of JAK1 was confirmed by Western blot analysis.

Measurement of IL-6 and sIL-6R concentrations in culture supernatant
MPM cells were cultured in 6-well plates at a density of 1 x 10^5 cells per well and incubated in RPMI 1640 medium containing 0.5% FCS. The concentrations of IL-6 and sIL-6R in the 24-hr culture supernatant were measured by means of Quantikine Colorimetric Sandwich ELISA (R&D Systems, Minneapolis, MN).

SDS-PAGE and western blot analysis
Whole cell protein extract was prepared from MPM cells in RIPA buffer (10 mmol/L Tris-HCl (pH 7.5), 150 mmol/L NaCl, 1% (v/v) NP-40, 0.1% (w/v) SDS, 0.5% (w/v) sodium deoxycholate, 1 mmol/L Na3VO4, and 1% protease inhibitor cocktail (Roche Applied Science, Indianapolis, IN)). Extracted proteins were resolved on SDS-PAGE and transferred to an Immobilon-P Transfer membrane (Millipore, Bedford, MA). The following antibodies were used: antiphospho-STAT3, 1:1,000; anti-p53 antibody (Cell Signaling Technology) was added to the lysate followed by overnight incubation at 4°C. Protein G Sepharose (GE Healthcare Bio-Sciences) was then added and incubated by end-over-end mixing for 2 hr. The beads were washed five times in RIPA buffer and analyzed by Western blotting.

Phospho-kinase array
Expression of phosphorylated proteins was detected with the Proteome Profiler™ Human Phospho-Kinase Array kit (R&D Systems). The procedures were performed according to the manufacturer’s protocol using 400 μg protein lysate per array.

MTS assay
MPM cell lines were plated in 96-well plates at a density of 1,000 cells per well and incubated in RPMI 1640 medium containing 10% FCS. After a three-day culture, cell proliferation was evaluated with the 3-(4,5-dimethylthiazol-2-yl)-5-(3-carboxymethoxyphenyl)-2-(4-sulfophenyl)-2H-tetrazolium (MTS) assay (CellTiter 96 aqueous nonradioactive cell proliferation assay; Promega, Madison, WI). MTS color development was measured and analyzed with a microplate reader Model 680 (Bio-Rad Laboratories, Hercules, CA) at a wavelength of 450 nm with a reference wavelength of 750 nm. This assay was performed in triplicate.

Apoptosis assay
MPM cells were grown to confluence to attain synchronization in G1 and subcultured at a lower density (1 x 10^5 cells in a six-well plate) for 24 hr so that most of the cells were in the S phase. Adenoviral vectors were infected by distributing suspensions of AdSOCS3 or AdLacZ onto cells at a MOI of 40, followed by incubation at 37°C for an additional 72 hr. The cells were then trypsinized and collected with the supernatants, followed by determination of cell viability by means of annexin V and 7-amino-actinomycin D (7-AAD) staining (BD Biosciences, San Jose, CA) using the FACScanto flow cytometer (BD Biosciences). Data were analyzed with FlowJo software (Tree Star, Ashland, OR). This assay was performed in duplicate.

Cell cycle assay
MPM cells were grown to confluence to attain synchronization in G1 and subcultured at a lower density (1 x 10^5 cells in a six-well plate) for 24 hr so that most of the cells were in the S phase. Adenoviral vectors were infected by distributing suspensions of AdSOCS3 or AdLacZ onto cells at an MOI of 40, followed by incubation at 37°C for an additional 24 hr. The cells were then trypsinized and collected with the supernatants, after which the cell cycle was determined by means of propidium iodide (PI) staining according to the instructions for the Cycle Test Plus DNA Reagent kits (BD Biosciences) using the FACScanto flow cytometer. This assay was performed in duplicate.
Mouse xenograft model

All animal experiments were conducted according to the institutional ethical guidelines for animal experimentation of the National Institute of Biomedical Innovation (Osaka, Japan). Female ICR nu/nu mice, 6 to 7 weeks of age, were obtained from Charles River Japan (Yokohama, Japan). The mice were housed for 7 to 14 days and allowed ad libitum access to food and water.

For subcutaneous xenograft experiments, we injected $3 \times 10^6$ cells in a total volume of 100 $\mu$L of 1/1 (v/v) PBS/Matrigel (Becton Dickinson, Bedford, MA) in the flank of ICR nu/nu mice. When the tumor sizes reached $\sim 100 \text{ mm}^3$, $1 \times 10^8$ plaque-forming units (pfu)/50 $\mu$L of AdSOCS3 or AdLacZ was injected intratumorally twice per week. Tumor volumes were determined weekly by measuring in two dimensions, length ($L$) and width ($W$), and calculating volume as $(W^2 \times L)/2$.

For pleural xenograft experiments, cells were resuspended in PBS at a density of $1 \times 10^6$ cells in a total volume of 150 $\mu$L of 1/1 (v/v) PBS/Matrigel (Becton Dickinson). The mice were intrathoracically injected with 150 $\mu$L of the cell suspension through a 26-gauge needle. Seven, 14 and 21 days after cell inoculation, $5.0 \times 10^7$ plaque-forming units (pfu)/
150 μL of AdSOCS3 or AdLacZ was injected into the thoracic space with the same technique. Twenty-eight days after cell inoculation, the mice were sacrificed and their thoracic spaces examined macroscopically for growths, and tumors detected in the thoracic spaces were removed and weighed.

**Immunohistochemistry**
Tumors in the thoracic spaces were harvested and paraffin embedded for immunohistochemical analysis using anti-SOCS3 antibody (IBL). Terminal deoxynucleotidyl transferase-mediated dUTP nick-end labeling (TUNEL) assay (with DAPI nuclear counterstaining) for apoptosis was performed using the ApopTag® Fluorescein in situ Apoptosis Detection Kit (Chemicon International, Temecula, CA) according to the manufacturer’s instructions.

**Statistical analysis**
Data are shown as mean ± SD for the number of experiments indicated. Student’s t-test was used for comparison of the data. Differences were considered significant at p < 0.05.

**Results**
MRA treatment has no inhibitory effect on the growth of MPM cells
Reports of high-level expression of IL-6 in the pleural fluid of MPM patients prompted us to investigate the role of this signaling pathway in MPM. To characterize IL-6/sIL-6R levels secreted by MPM cell lines, we used sandwich ELISA for quantitation of IL-6/sIL-6R levels in 24-hr culture supernatants. As shown in Figure 1a, H226 and EHMES-1 were identified as cell lines with high IL-6/sIL-6R secretion.
Because it has been reported that IL-6 may represent a therapeutic target for tumorigenesis in MPM cells, we subsequently tested the effect of anti-IL-6R monoclonal antibody (MRA) treatment. For this analysis, we used H226 and EHMES-1 cells which secrete high levels of IL-6. Figure 1b shows that MRA did not inhibit cell growth in H226 and EHMES-1 cells. On the other hand, it has been reported that 25 μg/mL of MRA is required for sufficient growth suppression of Lennert’s lymphoma-derived T cells which show IL-6–dependent cell growth and we demonstrated that MRA inhibited IL-6-stimulated STAT3 phosphorylation in MPM cells (Fig. 1c). These results suggest that, although H226 and EHMES-1 cells secreted high levels of IL-6, IL-6 signaling had little effect on the growth of these cells. However, the role of STAT3 on cell growth in H226 and EHMES-1 cells was not clear since MRA treatment did not inhibit endogenous phosphorylated STAT3 levels in these cells.

Overexpression of SOCS3 inhibits the growth of MPM cells

The JAK/STAT3 pathway is an important signaling pathway negatively regulated by SOCS3. We therefore used a replication-defective recombinant adenoviral vector to investigate the regulation of MPM cell growth by SOCS3. As shown in Figure 2a, AdSOCS3 strongly inhibited cell growth in H226, EHMES-1, MESO-1 and MESO-4 cells, while the endogenous SOCS3 expression levels of MPM cells were higher than those of normal mesothelial cells (Fig. 2d). This indicates that overexpression of SOCS3 was required for growth inhibition of MPM cells. Because sufficient transduction efficiency of the adenovirus vector and strong expression of
SOCS3 were detected at an MOI of 40 in MPM cells (Figs. 2b and 2c), we performed subsequent experiments using AdSOCS3 at an MOI of 40.

**SOCS3 induces apoptosis and G0/G1 arrest in MPM cells**

Next, we investigated the mechanism by which AdSOCS3 inhibited cell growth in H226, EHMES-1, MESO-1 and MESO-4 cells. Since light microscopy findings suggested poor cell viability, apoptosis in these cells was tested by means of annexin V and 7-AAD staining using flow cytometry three days after the addition of AdSOCS3 to the culture. The results of flow cytometric analysis led to the identification of two types of cells: early apoptotic (Annexin V⁻7-AAD⁺) and late apoptotic (Annexin V⁺7-AAD⁻). Compared to treatment with AdLacZ, treatment with AdSOCS3 resulted in elevated...
Figure 5. SOCS3 regulates p53 expression in a STAT3-independent manner. (a) Growth curves of H226 and EHMES-1 cells treated with AddnSTAT3. Cells were infected with either AddnSTAT3 or AdLacZ as control at an MOI of 10–160. Cells were cultured in RPMI 1640 medium containing 10% FCS. After a 3-day culture, viable cell numbers were counted with the MTS assay. Figures show the average (points) of triplicate wells ± SD (bars). (b) Phospho-kinase array revealed that H226 cells treated with AdSOCS3 showed higher levels of phospho-p53 (Ser 392) and phospho-p53 (Ser 46) expression than those treated with AddnSTAT3 or AdLacZ. H226 cells were cultured in RPMI 1640 medium containing 0.5% FCS with AdSOCS3 at an MOI of 40. After 24 hr of culturing, protein extracts were examined with a phospho-kinase array with each phosphorylated protein identified in duplicate. The double-labeled spots in the upper right corner represent the positive controls. (c) p53 expression was induced by AdSOCS3. H226 cells were cultured in RPMI 1640 medium containing 0.5% FCS with AdSOCS3 at an MOI of 40. After 24 hr of culturing, protein extracts were probed with antiphospho-p53 (Ser 392), phospho-p53 (Ser 46), p53, phospho-STAT3, STAT3 and GAPDH antibody. (d) Influence of JAK1 siRNA on p53 expression. Either JAK1 siRNA or nonspecific siRNA as control was added to H226 cells. Cells were cultured in RPMI 1640 medium containing 0.5% FCS. After 48 hr of culturing, 100 ng/mL of IL-6 and 100 ng/mL of sIL-6R were added for 10 min. The protein extracts were probed with antiphospho-p53 (Ser 392), phospho-p53 (Ser 46), p53 and GAPDH antibody or immunoprecipitated with anti-JAK1 antibody and blotted with antiphosphotyrosine antibody (clone 4G10) and subsequently with anti-JAK1 antibody. (e) Expression of p53. RT-PCR was used to determine levels of p53 expression. (f) SOCS3 interacts with p53. H226 cells were cultured in RPMI 1640 medium containing 10% FCS with AdSOCS3 at an MOI of 40. After 24 hr of culturing, protein extracts were immunoprecipitated with anti-p53 antibody and immunoblotted with anti-SOCS3 antibody. (g) SOCS3 enhances p21 expression. H226 cells were cultured in RPMI 1640 medium containing 10% FCS with AdSOCS3 at an MOI of 40. After 12 hr of culturing, H226 cells were treated with doxorubicin (300 ng/mL) for 0–48 hr. Protein extracts were immunoblotted with anti-p21 antibody.
apoptosis in both early and late apoptotic subsets in H226, EHMES-1, Meso-1 and Meso-4 cells (Fig. 3a). Furthermore, cleaved caspase-3, one of the key molecules in apoptosis, was detected in whole cell extracts of H226, EHMES-1, Meso-1 and Meso-4 cells treated with AdSOCS3 (Fig. 3b). We therefore conclude that AdSOCS3 induced apoptosis in MPM cells.

In addition to apoptosis, cell cycle regulation is an important mechanism for inhibition of cell growth. To analyze the effect of AdSOCS3 on cell cycle regulation, we infected H226, EHMES-1, Meso-1 and Meso-4 cells with AdSOCS3 and then analyzed cell cycle distribution by means of flow cytometry. When H226 and Meso-4 cells were treated with AdSOCS3, the G0/G1 cell population increased more than in those treated with AdLacZ (Fig. 3c).

**SOCS3 inhibits JAK1, ERK and FAK signaling**

One of the important signaling pathways regulated by SOCS3 is the JAK/STAT3 pathway. We used JAK inhibitor I, which suppresses JAK2 signaling, to investigate the regulation of cell growth by JAK signaling pathways. For this assay, we used H226 and EHMES-1 cell lines (on which MRA had no growth inhibitory effect) to investigate the IL6-independent growth inhibitory effect by SOCS3. As shown in Figure 4a, only the growth of EHMES-1 cells, and not of H226 cells, was inhibited by JAK inhibitor I. This suggests that AdSOCS3 inhibited cell growth in H226 cells via signaling pathways which were not inhibited by JAK inhibitor I.

To identify the differences between the inhibitory effects of AdSOCS3 and JAK inhibitor I on JAK signaling pathways, we studied changes in the phosphorylation status of JAK1 in H226 cells treated with AdSOCS3 and JAK inhibitor I. Figure 4b shows that AdSOCS3 suppressed IL6-stimulated JAK1 phosphorylation, but that JAK inhibitor I did not affect it. These results lead us to propose that SOCS3 inhibited cell growth in H226 in part by means of negative regulation of JAK1.

We used JAK1 siRNA to evaluate the role of JAK1 signaling pathways in cell growth. As seen in Figure 4c, JAK1 siRNA inhibited cell growth in H226 and EHMES-1 cells, suggesting that the growth of H226 cells was partially regulated by JAK1 signaling.

Because it has been reported that SOCS3 inhibits the ERK and FAK signaling pathways, we examined these pathways in H226 and EHMES-1 cells. Figure 4d demonstrated that the growth of H226 and EHMES-1 cells was inhibited by the ERK inhibitor PD98059, while ERK phosphorylation was inhibited by AdSOCS3 in these cells (Fig. 4e). In addition, AdSOCS3 inhibited phospho-FAK and FAK in H226 and EHMES-1 cells (Fig. 4f). We therefore conclude that overexpression of SOCS3 regulates multiple signaling pathways in MPM cells.

**SOCS3 regulates p53 expression**

We next investigated the role of STAT3 in H226 and EHMES-1 cells and used AddnSTAT3 to examine the regulation of cell growth by STAT3 signaling pathways. As seen in Figure 5a, AddnSTAT3 inhibited cell growth in EHMES-1 cells but not in H226 cells. Since this suggests that STAT3 is not involved in the growth of H226 cells, we focused our study on signaling pathways independent of STAT3.

To identify the target molecules of SOCS3 in STAT3-independent pathways, we used a phospho-kinase array to evaluate the expression profile of phosphorylated proteins in H226 cells. Figure 5b shows that expression of phospho-p53 (Ser 392) and phospho-p53 (Ser 46) in H226 cells after treatment with AdSOCS3 was higher than in those treated with either AddnSTAT3 or AdLacZ. In addition to phospho-p53, p53 was also highly expressed when treated with AdSOCS3 (Fig. 5c). These results suggest that SOCS3 regulated p53 expression.

We next investigated whether JAK1 regulates p53 expression. To this end, we used JAK1 siRNA for the transfection of H226 cells and Western blotting for the examination of p53 expression. As shown in Figure 5d, silencing of JAK1 did not influence p53 expression, indicating that JAK1 and p53 are regulated by SOCS3 via independent pathways.

Since transfection with AdSOCS3 did not enhance transcription of p53 in H226 cells (Fig. 5e), we next investigated whether SOCS3 interacts with p53. After transfection of AdSOCS3 into H226 cells, we detected SOCS3 in the immunoprecipitate of a p53-specific antibody (Fig. 5f). In addition, SOCS3 enhanced the expression of p21 which was the target of p53 (Fig. 5g). Taken together, these findings suggest that SOCS3 interacts with p53 protein.

**SOCS3 exhibits antitumor activity in a mesothelioma xenograft model**

We also evaluated the therapeutic effect of AdSOCS3 injection on the growth of subcutaneously or intrathoracically implanted MPM cells in ICR nu/nu mice. Of the MPM cell lines used in our study, we were able to establish H226 and Meso-4 xenograft models. Injection of AdSOCS3 vector (1 × 10^8 pfu/50 μL) intratumorally twice per week reduced tumor volumes compared to tumor volumes in control AdLacZ-injected animals (Fig. 6a). Preliminary experiments revealed that when 1 × 10^6 MPM cells (H226 or Meso-4) were inoculated into the thoracic space, dissemination of tumors was observed in all mice 28 days after cell implantation. Injection of the AdSOCS3 vector (5 × 10^7 pfu/150 μL) into the thoracic cavity 7, 14 and 21 days after the implantation of 1 × 10^6 MPM cells (H226 or Meso-4), reduced the weight of tumor nodules compared to the weight of those in control AdLacZ-injected animals (Figs. 6b and 6c). Finally, Western blot and immunohistochemical analysis indicated that SOCS3 was overexpressed and induced apoptosis in the
Figure 6. SOCS3 exhibits antitumor activity in a mesothelioma xenograft model. (a) Female ICR nu/nu mice were intratumorally treated with $1 \times 10^8$ pfu of AdSOCS3 or AdLacZ twice per week after the implantation of $3 \times 10^6$ H226 or MESO-4 cells subcutaneously in the flank of mice. Tumor volumes were determined weekly. Figures show the average (points) for five animals ± SD (bars). (b) Gross appearance of H226 and MESO-4 tumors grown orthotopically in the thoracic spaces. Female ICR nu/nu mice were intrathoracically treated with $5 \times 10^7$ pfu of AdSOCS3 or AdLacZ for 7, 14 and 21 days after the implantation of $1 \times 10^6$ H226 or MESO-4 cells into the pleural space. After 28 days of tumor cell inoculation, the animals were sacrificed and pleural dissemination of the tumor cells was assessed. (c) Each tumor nodule found in the thoracic spaces was also weighed. Figures show the average (columns) for eight animals ± SD (bars). (d) Western blot analysis of SOCS3 and cleaved caspase-3 in H226 tissue from AdSOCS3-injected animals (left panel). The H226 cell bearing animals were treated with AdSOCS3 on day 7 and sacrificed on day 10. The thoracic tumors were analyzed by Western blot. Immunohistochemical analysis of SOCS3 and TUNEL (blue fluorescence = DAPI staining for nuclei; cyan fluorescence = TUNEL positivity) in H226 tissue from AdSOCS3-injected animals (right panel). The animals were treated in the same way as described above.
H226 tissue from AdSOCS3-injected animals (Fig. 6d). Immunohistochemical analysis of SOCS3 overexpression and apoptosis in MESO-4 tissue could not be clearly determined, however Western blot analysis showed identical results to that observed in H226 tissue (data not shown). From these results, we conclude that SOCS3 exhibits antitumor activity not only in vitro but also in vivo in the MPM model. We hope that these findings may lead to the successful clinical application of SOCS3 for MPM treatment.

**Discussion**

Malignant mesothelioma represents a great challenge to both clinicians and researchers due to its poor prognosis and remarkable resistance to current therapies. Although there have been some improvements in treatment over the past few years, a better understanding of the molecular basis of the disease and of how to improve treatment is required. Among molecular targeted therapies, recently developed tyrosine kinase inhibitors have been tested for MPM but without therapeutic benefit. This is partially explained by the fact that multiple receptor tyrosine kinases are frequently activated in MPM cells. In our study, we showed that SOCS3 inhibited the proliferation of MPM cells through multiple signaling pathways including JAK/STAT3, ERK, FAK and p53 pathways. We observed that SOCS3 did not influence the expression and activation of p38, JNK, Akt or GSK3β proteins in H226 and EHMES-1 cell lines (data not shown). Specifically, we were able to demonstrate that AdSOCS3 inhibits MMP progression in a mouse pleural xenograft model. These data provide new insights into the clinical application of SOCS3 gene delivery for the treatment of MPM.

We also provided evidence that MRA had little effect on proliferation of MPM cells. A recent study by Adachi et al. found that MRA is capable of blocking IL-6 signaling and suppresses the cell growth of MMP induced by IL-6/sIL-6R. We hypothesize that MRA was not able to inhibit proliferation of these cells because it did not inhibit signals from other cytokines acting through gp130 or endogenous activated molecules downstream of gp130 involved in proliferation of these cells.

There are several JAK inhibitors, including JAK inhibitor I, but these inhibitors inhibit JAK1 less than they do other JAK family molecules. This may explain why, although JAK1 is involved in H226 cell proliferation, JAK inhibitor I had little effect on proliferation of H226 cells. SOCS3, however, is an effective JAK1 inhibitory molecule and also inhibits proliferation of H226 cells. It has further been reported that JAK2 inhibitors have antitumor effects on various cancer cells. Because of its pan-JAK inhibitory effect, SOCS3 appears to be a promising antitumor molecule.

We were able to show that SOCS3 regulated phospho-p53 (Ser392 and Ser46) and total p53 expression. Functional inactivation of the p53 pathways appears to be a critical requirement for the development of several human cancers. In spite of the fact that mutations in p53 are among the most commonly acquired genetic lesions seen in cancers, p53 mutations are rarely seen in MPM including H226 cells. It has been reported that Ser392 phosphorylation may regulate the oligomerization of p53 and thus its sequence-specific DNA binding, while phosphorylation of Ser46 has been implicated in the activation of p53-dependent apoptotic responses. The most thoroughly characterized downstream target of p53 activation is the induction of p21 expression, with p21 playing a critical role in the cell cycle checkpoint. In our study, moreover, SOCS3 enhanced p21 expression and induced apoptosis and G0/G1 arrest in MPM cells. In view of these results, we propose that SOCS3 induces apoptosis as well as G0/G1 arrest partially through the p53 pathways in MPM cells.

Recently, it has been reported that SOCS1 activates p53 via a direct interaction between the SH2 domain of SOCS1 and the N-terminal transactivation domain of p53, while we were able to show that SOCS3 did not enhance transcription of p53 but interacted with p53. It is thus conceivable that the observed interaction of SOCS3 with p53 may in turn enhance p53 protein stability. Such a mechanism may therefore involve the inhibition of interaction of p53 with other proteins that promote p53 protein degradation.

In our study, we used adenoviral SOCS3 gene transfer to the thoracic cavity in a mouse xenograft pleural tumor model to provide evidence of a potent antitumor effect of SOCS3 in vivo. Because MPM locates within the thoracic cavity and rarely displays widespread metastasis, gene transfer to the thoracic cavity makes this tumor uniquely accessible, thus facilitating the direct administration of novel therapeutic agents and subsequent analysis of treatment effects. Clinical trials involving intrapleural administration of adenoviral vectors to MPM patients have demonstrated that intrapleural gene therapy using adenoviral vectors is safe and well tolerated by MPM patients.

In conclusion, we demonstrated the antitumor effect of SOCS3 against MPM both in vitro and in vivo. The results of clinical application of SOCS3 for MPM treatment are eagerly anticipated.
